## Project 1

Alex Ho

16. september 2016

### 1 Introduction

We will in this project solve the one-dimensional Poisson equation, given as

$$-u''(x) = f(x) \quad (1)$$

numerically, with Dirichlet boundary conditions by rewriting the Poisson equation to a set of linear equations. In this project, we will also focus on memory allocation, floating point operations in our numerical algorithm and compare the algorithms that we use in the project. The method section is divided in multiple parts, where each part has a different task to be solved.

### 2 Method

#### a) Rewriting to a set of linear equations

We can discretize the Poisson equation as

$$\begin{aligned} -v''(x) &= f(x) \\ \implies -\frac{v_{i+1} + v_{i-1} - 2v_i}{h^2} &= f_i \end{aligned} \quad (2)$$

Where  $f_i = f(x_i)$ ,  $v_{i+1} = v(x_{i+1})$ , etc. for  $i = 1, 2, \dots, n$ . Multiply  $h^2$  on both sides, we get the following

$$2v_i - v_{i+1} - v_{i-1} = \tilde{f}_i, \quad \tilde{f}_i = h^2 f_i \quad (3)$$

Since this is for  $i = 1, 2, \dots, n$ , one can write this as a set of linear equations

$$\begin{aligned} 2v_1 - v_2 &= \tilde{f}_1 \\ 2v_2 - v_3 - v_1 &= \tilde{f}_2 \\ 2v_3 - v_4 - v_2 &= \tilde{f}_3 \\ &\vdots \\ 2v_n - v_{n-1} &= \tilde{f}_n \end{aligned} \tag{4}$$

We know from the boundary conditions that  $v_0 = v_{n+1} = 0$ , so we do not include them in the algorithm. We can clearly see a pattern here. This set of linear equation can be written in the form

$$\mathbf{A}\mathbf{v} = \tilde{\mathbf{f}} \tag{5}$$

Where

$$\mathbf{v} = \begin{pmatrix} v_1 \\ v_2 \\ \vdots \\ v_n \end{pmatrix} \quad \tilde{\mathbf{f}} = \begin{pmatrix} \tilde{f}_1 \\ \tilde{f}_2 \\ \vdots \\ \tilde{f}_n \end{pmatrix} \tag{6}$$

And the tridiagonal  $n \times n$  matrix as

$$\mathbf{A} = \begin{pmatrix} 2 & -1 & 0 & \dots & \dots & 0 \\ -1 & 2 & -1 & 0 & \dots & \dots \\ 0 & -1 & 2 & -1 & 0 & \dots \\ \dots & \dots & \dots & \dots & \dots & \dots \\ 0 & \dots & \dots & -1 & 2 & -1 \\ 0 & \dots & \dots & 0 & -1 & 2 \end{pmatrix} \tag{7}$$

We are also given the source term as  $f(x) = 100e^{-10x}$  and that the closed-form solution, given the same interval and boundary conditions, is  $u(x) = 1 - (1 - e^{-10})x - e^{-10x}$ . This can easily be shown:

$$\begin{aligned} -u''(x) &= -\frac{d^2}{dx^2} (1 - (1 - e^{-10})x - e^{-10x}) \\ &= -\frac{d}{dx} ((1 - e^{-10}) + 10e^{-10x}) \\ &= -(-100e^{-10x}) = f(x) \end{aligned} \tag{8}$$

## b) Forward and backward substitution

Our matrix  $\mathbf{A}$  can be written in terms of one-dimensional vectors  $a, b$  and  $c$  with the length  $i = 1 : n$ . The linear equation is then

$$\begin{pmatrix} b_1 & c_1 & 0 & \cdots & \cdots & \cdots \\ a_1 & b_2 & c_2 & 0 & \cdots & \cdots \\ 0 & a_2 & b_3 & c_3 & 0 & \cdots \\ & 0 & \cdots & \cdots & \cdots & \cdots \\ & & & a_{n-2} & b_{n-1} & c_{n-1} \\ & & & & a_{n-1} & b_n \end{pmatrix} \begin{pmatrix} v_1 \\ v_2 \\ v_3 \\ \vdots \\ v_{n-1} \\ v_n \end{pmatrix} = \begin{pmatrix} \tilde{f}_1 \\ \tilde{f}_2 \\ \tilde{f}_3 \\ \vdots \\ \tilde{f}_{n-1} \\ \tilde{f}_n \end{pmatrix} \quad (9)$$

We want to write an algorithm to solve the values of  $v_i$ , assuming different values for the matrix elements  $a_i, b_i, c_i$ . We also want to find the number of floating point operations (FLOPS) that is needed to solve the given algorithm.

Let us start by writing out the linear equation to be in the form similar to (5)

$$b_1 v_1 + c_1 v_2 = \tilde{f}_1 \quad (10)$$

$$a_1 v_1 + b_2 v_2 + c_2 v_3 = \tilde{f}_2 \quad (11)$$

$$a_2 v_2 + b_3 v_3 + c_3 v_4 = \tilde{f}_3 \quad (12)$$

$$\vdots$$

$$a_{n-2} v_{n-2} + b_{n-1} v_{n-1} + c_{n-1} v_n = \tilde{f}_{n-1} \quad (13)$$

$$a_{n-1} v_{n-1} + b_n v_n = \tilde{f}_n \quad (14)$$

Starting with (10) and (11), we first multiply (10) with  $a_1/b_1$  and then subtract (11) with the new (10) (after the multiplication), we get

$$a_1 v_1 + \frac{c_1 a_1}{b_1} v_2 = \tilde{f}_1 \frac{a_1}{b_1} \quad (15)$$

$$a_1 v_1 + b_2 v_2 + c_2 v_3 - (a_1 v_1 + \frac{c_1 a_1}{b_1} v_2) = \tilde{f}_2 - \tilde{f}_1 \frac{a_1}{b_1} \quad (16)$$

Multiply  $b_1/a_1$  on (15), and with a little rewriting we arrive to

$$b_1 v_1 + c_1 v_2 = \tilde{f}_1 \quad (17)$$

$$\tilde{b}_2 v_2 + c_2 v_3 = \tilde{f}_2 \quad (18)$$

Where I have now defined  $\tilde{b}_2 = b_2 - \frac{c_1 a_1}{b_1}$  and  $F_2 = \tilde{f}_2 - \tilde{f}_1 \frac{a_1}{b_1}$ . Let us now continue by looking at (12) and (19), that is

$$\tilde{b}_2 v_2 + c_2 v_3 = F_2 \quad (19)$$

$$a_2 v_2 + b_3 v_3 + c_3 v_4 = \tilde{f}_3 \quad (20)$$

Doing the same trick as we did previously, we multiply  $a_2/\tilde{b}_2$  on equation (19) and then subtract that on (20). Rewriting a little bit we end up with

$$\tilde{b}_2 v_2 + c_2 v_3 = F_2 \quad (21)$$

$$\tilde{b}_2 v_3 + c_3 v_4 = F_3 \quad (22)$$

Here I have defined  $\tilde{b}_3 = b_3 - \frac{c_2 a_2}{b_2}$  and  $F_3 = \tilde{f}_3 - F_2 \frac{a_2}{b_2}$ . One can continue to do this, but we can clearly see a pattern here, which results to these general expressions

$$\tilde{b}_i = b_i - \frac{c_{i-1} a_{i-1}}{\tilde{b}_{i-1}} \quad (23)$$

$$F_i = \tilde{f}_i - F_{i-1} \frac{a_{i-1}}{\tilde{b}_{i-1}}, \quad \text{for } i = 2, \dots, n \quad (24)$$

This is known as *Forward Substitution*. For  $i = 1$ , we need to explicitly define that  $\tilde{b}_1 = b_1$  and  $F_1 = \tilde{f}_1$ . This is mostly because values like  $c_0$  and  $a_0$  are outside our interval.<sup>1</sup> The number of floating point operations (FLOPS) for these two steps combined is 6 FLOPS. Both steps do one subtraction, one multiplication and one division, which means that each of them do 3 FLOPS, and the total will therefore be 6 FLOPS.

The next step is to find an algorithm to find the values of  $v_i$ . From the calculations above, our linear equations are as following

$$b_1 v_1 + c_1 v_2 = \tilde{f}_1 \quad (25)$$

$$\tilde{b}_2 v_2 + c_2 v_3 = F_2 \quad (26)$$

$$\tilde{b}_3 v_3 + c_3 v_4 = F_3 \quad (27)$$

$\vdots$

$$\tilde{b}_{n-1} v_{n-1} + c_{n-1} v_n = F_{n-1} \quad (28)$$

$$\tilde{b}_n v_n = F_n \quad (29)$$

---

<sup>1</sup>Not to be confused with the index notation in C++ and Python, where intervals goes as  $x_0, x_1, \dots, x_{n-1}$

From (29) we have that  $v_n = F_n/\tilde{b}_2$ , which is the "initial" value of  $v$  and we will have to calculate backwards to get all the values of  $v_i$ . Equation (28) gives us the relation:

$$v_{n-1} = \frac{1}{\tilde{b}_{n-1}} (F_{n-1} - c_{n-1}v_n)$$

In terms of  $i$ 's, this will become

$$v_{i-1} = \frac{1}{\tilde{b}_{i-1}} (F_{i-1} - c_{i-1}v_i), \quad \text{for } i = n, n-1, \dots, 2 \quad (30)$$

This is known as *Backward Substitution*. The number of FLOPS in this case will be 3 FLOPS. Like Forward substitution, we have one subtraction, one multiplication and one division. The number of FLOPS for both Forward substitution and Backward substitution is 9 FLOPS. We also have to keep in mind that we do these calculations  $n$  times, so the total number of FLOPS for all  $n$  equations is  $9n$  FLOPS.

### c) Specialized algorithm

We now use the fact that our matrix  $\mathbf{A}$  has identical matrix elements along the diagonal and the non-diagonal elements are also identical (but different from the diagonal one). With our specific tri-diagonal matrix  $\mathbf{A}$ , we will specialize our algorithm from the previous task to solve our linear equation.

Let us first look at the forward substitution algorithm for  $\tilde{b}_i$ , we had

$$\tilde{b}_i = b_i - \frac{c_{i-1}a_{i-1}}{\tilde{b}_{i-1}} \quad (31)$$

With the non diagonal elements as  $a_i = c_i = -1$  and  $b_i = 2$ . With the initial value  $\tilde{b}_1 = b_1 = 2$ , we can write out every  $\tilde{b}_i$  value, but after a few steps, one

can see a pattern and we end up with

$$\begin{aligned}
\tilde{b}_2 &= 2 - \frac{1}{2} = \frac{3}{2} \\
\tilde{b}_3 &= 2 - \frac{1}{\frac{3}{2}} = \frac{4}{3} \\
\tilde{b}_4 &= 2 - \frac{1}{\frac{4}{3}} = \frac{5}{4} \\
&\vdots \\
\tilde{b}_i &= \frac{i+1}{i}, \quad \text{for } i = 1, 2, \dots, n
\end{aligned} \tag{32}$$

The next step in the forward substitution algorithm is then

$$\begin{aligned}
F_i &= \tilde{f}_i - F_{i-1} \frac{a_{i-1}}{\tilde{b}_{i-1}} \\
\implies F_i &= \tilde{f}_i + \frac{F_{i-1}}{\tilde{b}_{i-1}}, \quad \text{for } i = 2, \dots, n
\end{aligned} \tag{33}$$

Where the initial value is  $F_1 = \tilde{f}_1$ . Finally, the backward substitution algorithm can be simplified to

$$\begin{aligned}
v_{i-1} &= \frac{1}{\tilde{b}_{i-1}} (F_{i-1} - c_{i-1} v_i) \\
\implies v_{i-1} &= \frac{1}{\tilde{b}_{i-1}} (F_{i-1} + v_i), \quad \text{for } i = n, n-1, \dots, 2
\end{aligned} \tag{34}$$

With the initial value  $v_n = F_n / \tilde{b}_n$ . The number of FLOPS for all three steps is 2 FLOPS. Each of them do one addition and one division. However, since the values of  $\tilde{b}_i$  is calculated beforehand, we do not have to take into account the calculations of these values, as they can be vectorized and quickly calculated in C++. Therefore, the number of FLOPS is only calculated by the second part of the forward substitution and backward substitution. Because of this, and keeping in mind that we are solving these equations  $n$  times, then the total number of FLOPS is  $4n$  FLOPS.

### d) Calculating relative error

We are tasked to calculate the relative error given as

$$\epsilon_i = \log_{10} \left( \frac{v_i - u_i}{u_i} \right)$$

as a function of  $\log_{10}(h)$ . Different values of  $h$  corresponds to different values of  $n$ . We will in this project use the values of  $n$  from  $n = 10$  up to  $n = 10^7$ .

### e) LU-decomposition

The LU-decomposition is done by using the *lib.cpp* file that is provided this course.

## 3 Implementation

I have used both C++ and Python to solve this project. The strategy is to use C++ to develop and algorithm, do the calculations and save the results to a text file. Once I have the results, I use Python to plot the values that was calculated in C++. All files for this project can be found in the GitHub repository [https://github.com/AHo94/FYS3150\\_Projects/tree/master/Project1](https://github.com/AHo94/FYS3150_Projects/tree/master/Project1).

For the general algorithm, I will assume that the values along the diagonal are the same. This is to compare the results between the general and special method.

Since we are only calculating the values of  $i = 1, \dots, n$ , I have ignored the points at  $i = 0$  and  $i = n + 1$  in the C++ program. To compensate for that (and also to make sure we have the boundaries), I will have to add these points after the data calculations. This is done in the Python script, where I increase the array by 2 and then set the boundary conditions.

One important note is that the indexes in C++ and Python runs through  $i = 0$  to  $i = n - 1$ . So equations like equation (32) has to be modified with respect to this, so calculating  $\tilde{b}_i$  for the special case is in C++

$$\tilde{b}_i = \frac{i + 2}{i + 1}, \quad \text{for } i = 0, 1, \dots, n - 1 \quad (35)$$

$x$	$v_g$	$v_s$	$v_{LUD}$

0.909091	0.0848319	0.0848319	0.0848319

Tabell 1: Comparison of calculated data between the general  $v_g$  algorithm, special  $v_s$  algorithm and LU-decomposition  $v_{LUD}$  for  $n = 10$  points.

## 4 Results

Figure (1) and (2) shows the results of the dataset in the general algorithm. As we can see, the algorithm starts to converge from below to the exact solution. As we increase the number of points, the algorithm yields practically the same data points as the exact solution. Plots for  $n = 10^4, 10^5$  and  $10^6$  can be found in the GitHub repository under the Data\_plots folder.

Figure (3) and (4) shows the results from the specialized algorithm, where we know the diagonal elements beforehand. There is in fact nothing different here as both methods gave the same results (see table 1).

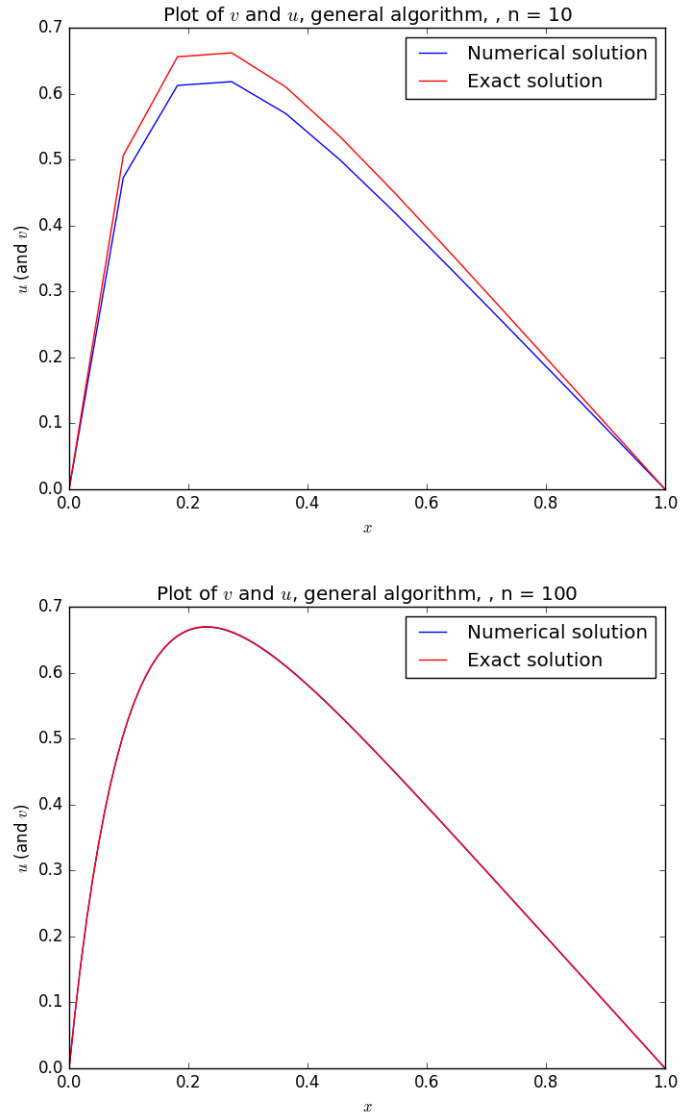

Figure (5) Shows the relative error between  $u_i$  and  $v_i$  for different step lengths (equivalent to different values of  $n$ ). Both axes are plotting in  $\log_{10}$  scale. The results seems a little weird to me, as I expect more of a  $v$ -like shape for the relative error. Table (1) shows the values of the relative error.

The LU-decomposition has not been plotted, as the dataset from this algorithm is exactly the same as the general and special algorithm that I developed. Table (1) shows the calculated data from these methods. The dataset can be found in the following GitHub link: [https://github.com/AHo94/FYS3150\\_Projects/tree/master/Project1/build-Project1\\_cpp-Desktop\\_Qt\\_5\\_7\\_0\\_MinGW\\_32bit-Debug](https://github.com/AHo94/FYS3150_Projects/tree/master/Project1/build-Project1_cpp-Desktop_Qt_5_7_0_MinGW_32bit-Debug)

The CPU time of these three methods are shown in blue text below:

Time elapsed for general algorithm: 5.3e-005s

Figur 1: Graphs showing the results of the general algorithm as a function of  $x$ , for  $n = 10$  and  $100$

Figure 2: Graph showing the result of the general algorithm as a function of  $x$ , with  $n = 1000$

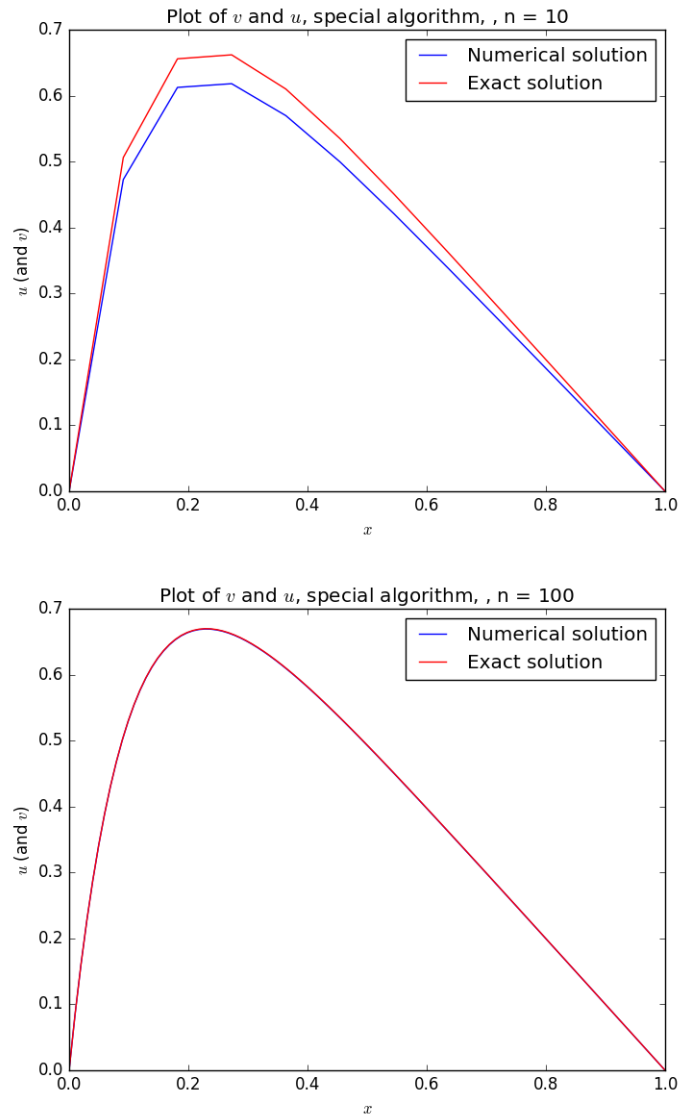

```
Time elapsed for specialized algorithm: 1e-005s
Time elapsed for LU-decomp: 14s
```

For the special algorithm, I have only calculated the CPU time for the  $n = 10, 100, 1000$  calculations it has done and ignored calculations with  $n = 10^4, 10^5, 10^6$ . It would obviously take a longer time to compute the data if we have more points, so comparing the same amount of calculations would set a better example.

As we can see, the general algorithm takes slightly more time to finish compared to the special algorithm. This is not surprising to us, as the special method do less FLOPS. The LU-decomposition, on the other hand, takes a lot longer time to finish its calculation.

## 5 Conclusion

From the results, we can clearly see that using LU-decomposition is not an ideal way to solve our linear equations, given that we know that our matrix  $\mathbf{A}$  is a tridiagonal matrix. The best method for our matrix  $\mathbf{A}$  was the specialized method that we implemented.

Figur 3: Graphs showing the results of the specialized algorithm as a function of  $x$ , for  $n = 10$  and 100

Figure 4: Graph showing the result of the specialized algorithm as a function of  $x$  with  $n = 1000$

Figure 5: Plot of the relative error as a function of  $\log_{10}(h)$

However, the algorithm for the special case was not a whole lot faster than the general algorithm. So, even if the elements along the diagonal were not the same, the general algorithm would still work incredibly well if our matrix is tridiagonal.

But what happens if the matrix is no longer tridiagonal? The general algorithm will no longer work, and we would have to use LU-decomposition to solve the linear equations.
